Each object in this array represents a fruit and is constructed to only store the weight of the fruit in each object. I must create an operator overload function to calculate the average weight of a collection of fruit. In my overloaded function, I calculate the average weight by dividing the sum of the objects in the collection by the number of objects. If I calculate the average weight of an empty collection, it should return an integer value of 0. Here is my code: class fruit { public: int weight; fruit(int weight):weight(82157476af
